

# Training Patch Analysis and Mining Skills for Image restoration Deep Neural Networks

Abstract

Problem: Network architecture development paradigm  $\rightarrow$  자원 효율성  $\downarrow$ , real-world 적용  $\downarrow$

Solution: patch selection guideline NAS

Conclusion

- ① patch extraction guideline is below
- ② 실제 NAS architecture 개발 NAS 못지 않음

## I. Intro

실험조건 개관

supervised learning: small-size  $\rightarrow$  overfitting, computational data

semi/weakly supervised

unsupervised learning: domain adaptation method

active learning:

이러 self-supervised learning이 문제: architecture가 중요

$\therefore y = Hx + n \rightarrow$  noise image 어떻게 생성

핵심 question 7개

답변은 V. Experiments 참조!

Motivation ① 자원 효율성  $\downarrow$

② 학습량  $\downarrow$   $\therefore$  low-frequency data  $\nearrow$

Contribution ① 이 질문이 위한 답변

② patch extraction guideline

③ verify guideline is useful

## II. Related work

A. Image Restoration based on Deep Networks

- image denoising: PnCNN, FFDNet, Two-stage networks, denoisers for real-world images
- super-resolution: development of architecture, NAS approach (FASR, DISR)

B. Data-relevant Strategies for Deep Networks

- property of training images is important
- patch-size  $\uparrow \Rightarrow$  performance  $\uparrow$
- image quality  $\uparrow \Rightarrow$
- hard example mining: deep metric learning
- active learning: efficiently train (budget  $\downarrow$ )

## III. Backgrounds

A. Image Restoration

- image denoising  $y = x + n$
- image super-resolution  $y = (x * k) \downarrow_s + u$

## IV. Settings

A. Environments and Comparisons

- Network Architecture: EDSR baseline
- Training Dataset: DIV2K, 191,300 patches, label patch-size 96x96 stride 40
- Representative Values: uncertainty (=loss), mean gradient magnitude, std of a patch, high frequency power (=power)

B. patch statistics

## V. Experiments

A. Evaluations ( # of patches: 10k ~ 150k)

① overfitting: patch-size가 < 30K 이면 성능이 data augmentation X

② geometric augmentation: 정규분포로 0.5dB 이내 PSNR

③ number of training patches  $\leq$  greenlight best (cannot look)

④ patch를 계속 쓰는 것만으로도 성능이 성능 best

⑤ hard sample가 복귀 성능은 무관.

(because regression task는 outlier-민감  $\rightarrow$  성능  $\downarrow$ )

⑥ scaling factor  $x_2, x_3, b = 25$   $\leftarrow$  모두 성능  $\downarrow$  (가장 성능이 무관)

⑦ model size와 # of training patches 상관  $\downarrow$

B. proposed Mining Skills

- ① stride는 patch-size보다 크게 설정 (non-overlap)
- ② max gradient magnitude가 큰 patch 추출한 것만 (1/1)
- ③ data augmentation 생략함 (of: Flip, rotation)

## VI. Discussion

A. Comparison with Benchmarks: 성능  $\neq$  a better

B. Result of Image Denoising: Good criteria is best
